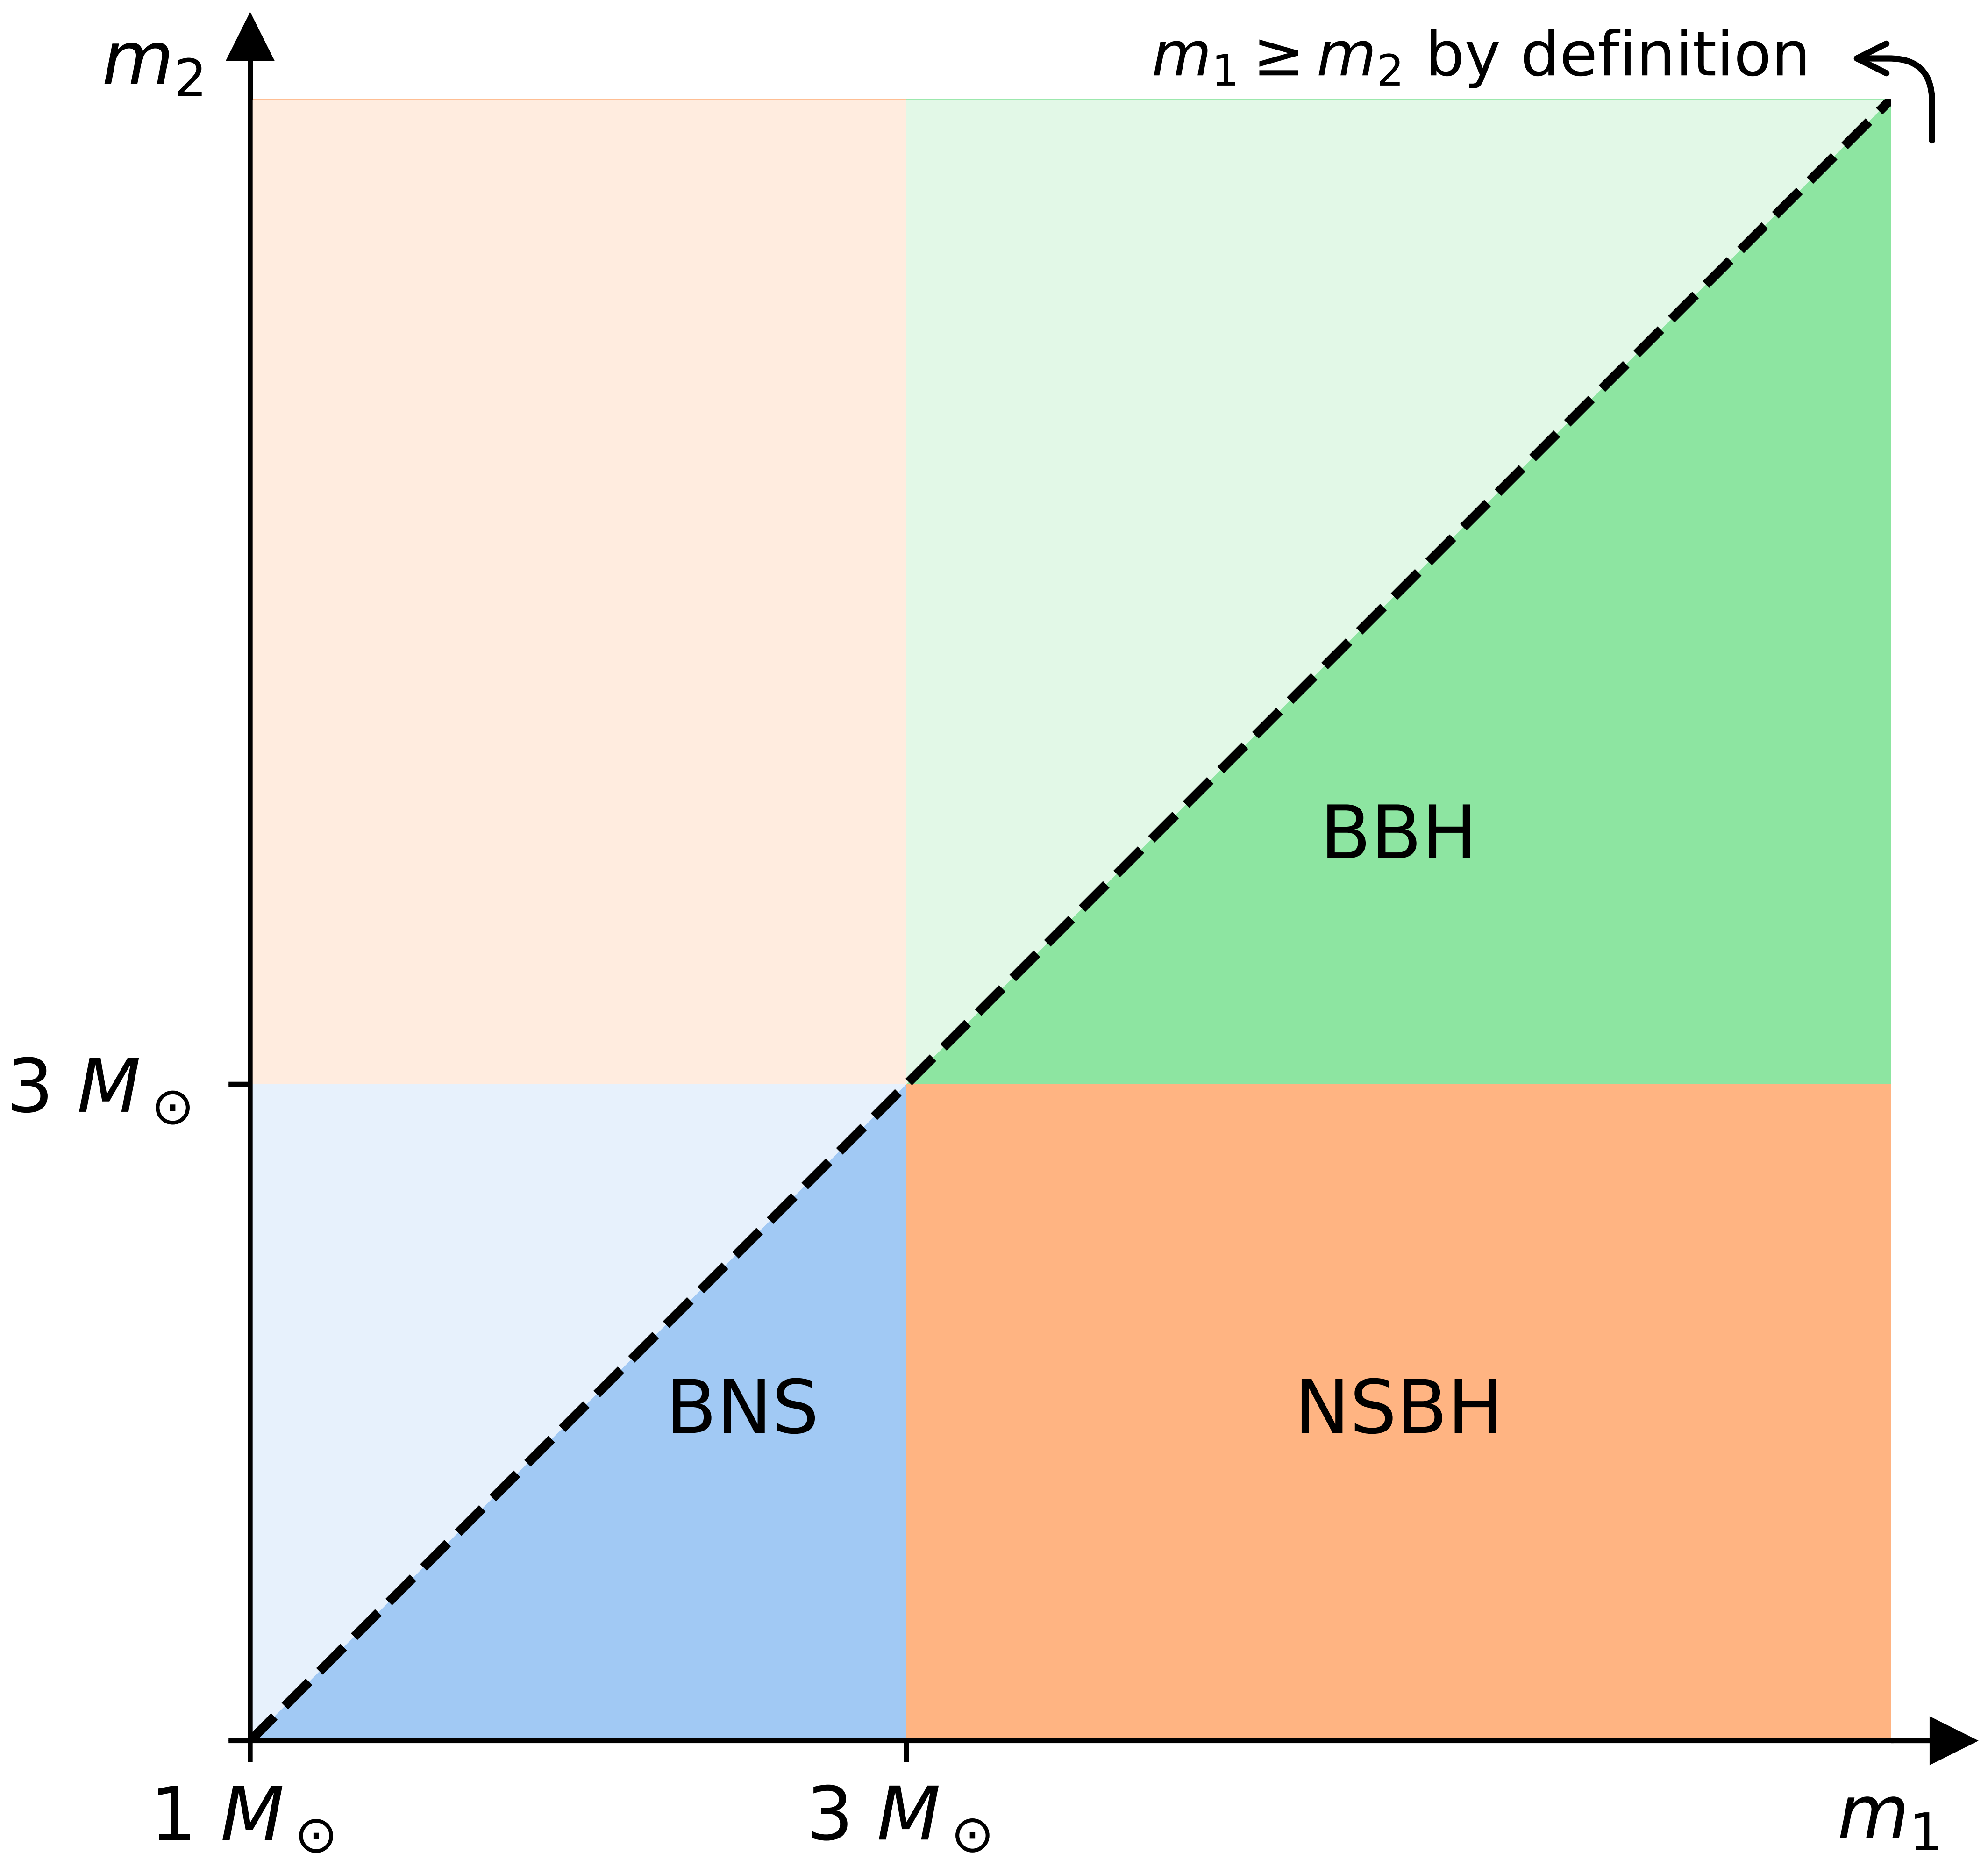
Digression on p_astro and EM_bright properties



Some useful definitions

Sky localization map: a file that contains a pixelated reconstruction of the joint distribution P(RA, Dec), plus a conditional posterior P(D_L | RA, Dec) on the luminosity distance. With these 3 info, we can fully build the 3D localization of the source

Sub Solar Mass search: there are now 2 pipelines (GstLAL and MBTA) that perform an additional search on mass ranges where we expect exotic objects:

$$0.2M_\odot < m_2 < 1.0M_\odot \text{ and } 0.2M_\odot < m_1 < 10M_\odot$$

<u>Caveat: an SSM search can also trigger on a BNS!!</u>

P(HasSSM) is also now released as part of IGWN alerts, if an SSM search triggers, reporting the probability that at least one has mass < 1 M_sun
